

Topic: Operations on Doubly Linked List

Q. Discuss the various operations (Traversal, Insertion, Deletion, Searching) on a Doubly Linked List. How does the presence of a 'previous' pointer change these operations compared to a Singly Linked List?

> **Definition to Remember**

> A **(previous
deletion**

Operations on Doubly Linked List

- **Forward Traversal:** Start at 'head', loop using 'temp = temp->next'.

- **B**

2. Insertion Operations

In a DLL, both 'next' and 'prev' pointers must be carefully updated.

| Position | Logic Steps |

| :--- | :

3. Deletion Operations

Deleting is highly efficient ($O(1)$) if a pointer to the target node ('del_node') is already known, because we don't need to traverse from the head to find its preceding node.

Logic to delete 'del_node':

1. If de

4. Advantages vs Disadvantages

Complete Executable C Code: Doubly Linked List Full Implementation

```
```c
```

#includ

```
struct Node {
```

int data

```
// Insert at Head - O(1)
```

struct l

```
if (head != NULL) head->prev = newNode;
```

return

```
// Forward & Backward Traversal
```

void tra

```
void traverseBackward(struct Node *head) {
```

if (hea

```
printf("Backward List: ");
```

```
while (
```

```
int main() {
```

```
struct l
```

```
head = insertHead(head, 30);
```

```
head =
```

```
traverseForward(head);
```

```
travers
```

```
return 0;
```

```
}
```
